

Reactive power compensation of supercapacitors in communication base stations

Overview

This paper introduces an optimised mathematical model which provides the configuration strategies of reactive power compensation and determines the optimal size of capacitor banks in the receiving converter . This paper introduces an optimised mathematical model which provides the configuration strategies of reactive power compensation and determines the optimal size of capacitor banks in the receiving converter . Installing static synchronous compensators (STATCOM) is one of the key methods to mitigate the issues of voltage fluctuation in converter stations connected to weak AC systems. Renewable energy sources are being embraced globally in an effort to reduce carbon footprints and combat climate change. At the same time, the proliferation of electric and . The E-STATCOM scheme composed of the Modular Multilevel Converter (MMC) and split supercapacitor energy storage has been proposed to improve the power compensation performance of the existing reactive power compensation system in the previous study. However, one of the main technical challenges . When reactive power devices, whether capacitive or inductive, are purposefully added to a power network in order to produce a specific outcome, this is referred to as compensation. It highlights the comparative advantages, limitations, and operational considerations of each method in the context of distribution networks. The study also addresses recent advancements, challenges, and .
